## 1 Multi-Armed Bandit

## 1.1 The Problem

#### **Example 1.1 -** *Motivating Example*

Consider having a group of patients and several treatments they could be assigned to. How best do you go about determining which treatment is best? The obvious approach is to assign some of the patients randomly and then assign the rest to the best treatment, but how much evidence is sufficient? And how likely are you to choose a sub-optimal treatment?

#### **Definition 1.1 -** Multi-Armed Bandit Problem

An agent is faced with a choice of K actions. Each (discrete) time step the agent plays action i they receive a reward from the random real-valued distribution  $\nu_i$ . Each reward is independent of the past. The distributions  $\nu_1, \ldots, \nu_K$  are unknown to the agent.

In the Multi-Armed Bandit Problem the agent seeks to maximise a measure of long-run reward.

#### Remark 1.1 - Informal Definition of Multi-Armed Bandit Problem

Given a finite set of actions and a random reward for each action, how best do we learn the reward distribution and maximise reward in the long-run.

#### **Definition 1.2 -** Formal Definition of Multi-Armed Bandit Problem

Consider a sequence of (unknown) mutually independent random variables  $\{X_i(t)\}_{i\in[1,K]}$ , with  $t\in\mathbb{N}$ . Consider  $X_i(t)$  to be the distribution of rewards an agent would receive if they performed action i at time t. Since the rewards are independent of the past  $X_i(t), X_i(t+1), \ldots$  are IID random variables. The Multi-Armed Bandit Problem tasks us to find the greatest expected reward from all the actions.

$$\mu^* := \max_{i=1}^K \mu_i$$
 where  $\mu_i = \mathbb{E}(X_i(t))$ 

There are a number of ways to formalise this objective.

## **Definition 1.3** - Strategy, $I(\cdot)$

Our agent's strategy  $I: \mathbb{N} \to [1, K]$  is a function which determines which action the agent shall make at a given point in time. The strategy can use the knowledge gained from previous actions & their rewards only.

$$I(t) = I\left(t, \underbrace{\{I(s)\}_{\in[1,t)}}_{\text{Prev. Actions}}, \underbrace{\{X_{I(s)}(s)\}_{\in[1,t)}}_{\text{Prev. Rewards}}\right) \in [1, K]$$

## **Definition 1.4 -** Long-Run Average Reward Criterion, $X_*$

For a strategy  $I(\cdot)$  we define the following measure for Long-Run Average Reward

$$X_* = \lim_{T \to \infty} \inf \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}(X_{I(t)})$$

The *Infinum* is taken as there is no guarantee the limit exists (depending on the strategy), typically we will only deal with strategies where this limit exists.

Most strategies as based only on realisations of  $\{X_i(s)\}_{s\in[1,t)}$ , thus  $\mathbb{E}(X_{I(t)}) \leq \mu^*$  and thus  $X_* \leq \mu^*$ . A strategy  $I(\cdot)$  is *Optimal* if  $X_* = \mu^*$ .

**Remark 1.2** - It is not hard to find an Optimal Strategy in the (very) long run, so we are going to look at Regret Minimisation First.

**Proposition 1.1 -** Mathematical Model & Assumptions for Multi-Armed Bandit Problem Model:

- $\bullet$  Bandit has K bernoulli arms.
- $X_i(t) \in \mathbb{R}$  is the reward obtained by played arm  $i \in [1, K]$  at time step  $t \in \mathbb{N}$ .

Assumptions:

- $X_1(\cdot), X_2(\cdot), \ldots$  are mutually independent sequences.
- For each  $i \{X_i(t)\}_{t\in\mathbb{N}}$  is a sequence of iid Bern $(\mu_i)$  random variables

We define the following quantities to make analysis easier

- $I(t) \in [1, K]$ . The index of the arm played in time t;
- $N_j(t) := \sum_{s=1}^t \mathbb{1}(I(s) = j)$ . The number of times arm j has been played in the first t rounds;
- $S_j(t) := \sum_{s=1}^t X_j(s) \mathbb{1}(I(s) = j)$ . The total reward from arm j in the first t rounds. This is a Binomial random variable independent  $Bin(N_j(t), \mu_j)$ ;
- $\hat{\mu}_{j,n} := \frac{S_j(t)}{N_i(t)}$ . The sample mean reward from arm j in the first n plays of arm j.

#### **Definition 1.5 -** Policy

A policy is a family of functions  $f_t$  which specify what arm is to be played in round t.  $f_t$  should depend on the information available at time t  $\{I(s), X_{I(s)}(s) : s \in [1, t-1]\}$ .

Randomised policies are allowed. So, in addition to the history up to time t,  $f_t$  can depend upon a  $U(t) \sim U[0,1]$  random variable which is independent of  $X_i(\cdot)$ . Thus

$$I(t) = f_t(\underbrace{I(1), \dots, I(t-1)}_{\text{arms chosen}}, \underbrace{X_{I(1)}(1), \dots, X_{I(t-1)}(t-1)}_{\text{observed rewards}}, \underbrace{U(t)}_{\text{randomness}})$$

We want to find the best policy (ie one which minimises the regret)

#### 1.2 Regret Minimisation

### **Definition 1.6** - Regret, $R_n$

Regret is a measure of how much reward was lost during the first n time steps. The Regret  $R_n$  of a strategy  $\{I(t)\}_{t\in\mathbb{N}}$  in the first n time steps is given by

$$R_{n} = \max_{k=1}^{K} \sum_{t=1}^{n} \mathbb{E}\left[\underbrace{X_{k}(t)}_{\text{Best Pos}} - \underbrace{X_{I(t)}(t)}_{\text{Actual}}\right]$$
$$= n\mu^{*} - \sum_{t=1}^{n} \mathbb{E}\left[X_{I(t)}(t)\right]$$

Regret only involves expectation and thus can be learnt from observations. We want to produce a strategy where Total Regret grows sub-linearly.(i.e.  $R_T/T \xrightarrow{T \to \infty} 0$ )

**Remark 1.3** - Minimising the growth rate of  $R_T$  with T is quite hard.

The best achievable regret scales as  $R_T \sim c \log T$  (i.e.  $R_T/c \log T \xrightarrow{T \to \infty} 1$ ) where c depends on the reward distributions  $X_1(t), \ldots, X_K(t)$ .

**Definition 1.7 -** Pseudo-Regret,  $\tilde{R}_n$ 

Pseudo-Regret  $\tilde{R}_n$  is a less popular alternative to Regret  $R_n$ . The Pseudo-Regret  $R_n$  of a strategy  $\{I(t)\}_{t\in\mathbb{N}}$  in the first n time steps is given by

$$\tilde{R}_n = \max_{k=1}^{K} \sum_{t=1}^{n} (X_k(t) - X_{I(t)}(t))$$

Pseudo-Regret includes intrinsic randomness (which is independent of the past) and thus cannot be learnt from observations.

## 1.3 Best Arm Identification for Bernoulli Distribution

Example 1.2 - Best Arm Identification for Bernoulli Bandits

Consider a bandit with two *Bernoulli* arms:  $\{X_1(t)\}_{t\in\mathbb{N}}$  IID RVs with distribution Bern $(\mu_1)$ ; and,  $\{X_2(t)\}_{t\in\mathbb{N}}$  IID RVs with distribution Bern $(\mu_2)$ .

Suppose  $\mu_1 > \mu_2$  (i.e. arm 1 is better). Let the player play each arm n times and declare the arm with the greatest empirical mean to be the better arm. What is the probability of choosing the wrong arm  $(Arm \ 2)$ ?.

An error occurs if  $\sum_{t=1}^{n} X_2(t) \ge \sum_{t=1}^{n} X_1(t)$  and thus we want to calculate the probability of this event.

Define  $\{Y(t)\}_{t\in\mathbb{N}}$  st  $Y(t) := \{X_2(t) - X_1(t)\}$ . This means  $Y(t) \in \{-1, 0, 1\} \subset [-1, 1]$ .

To use *Hoeffding's inequality* we need to scale Y to be in [0,1], so we define  $Z(t) := \frac{1}{2}(Y(t)+1)$ . We have  $\mathbb{E}(Z(t)) = \frac{1}{2}(1+\mu_2-\mu_1)$  and an error occurs if  $\sum_{t=1}^n Y(t) > 0 \iff \sum_{t=1}^n Z(t) \ge \frac{n}{2}$ . By *Hoeffding's Inequality* 

$$\mathbb{P}(\text{error}) = \mathbb{P}\left(\sum_{i=1}^{n} Z(t) \ge \frac{n}{2}\right)$$

$$= \mathbb{P}\left(\left(\sum_{i=1}^{n} Z(t)\right) - \frac{n}{2}(1 + \mu_2 - \mu_1) \ge \frac{n}{2}(\mu_1 - \mu_2)\right) \text{ subtracting } \mu \text{ from both sides}$$

$$= \mathbb{P}\left(\sum_{i=1}^{n} \left(X_i - \frac{1}{2}(1 + \mu_2 - \mu_1)\right) \ge n \frac{1}{2}(\mu_1 - \mu_2)\right) \text{ arranging for Hoeffding's}$$

$$\leq \exp\left(-2n \cdot \frac{1}{4}(\mu_1 - \mu_2)^2\right) \text{ by Hoeffding's Inequality}$$

$$= \exp\left(-\frac{n}{2}(\mu_1 - \mu_2)^2\right)$$

#### 1.4 Heuristic

Remark 1.4 - How many tests?

Suppose an agent is comparing two arms and is given a finite time horizon T after in which they must choose the best arm. The obvious strategy is to perform each task N times and then choose the arm with the greatest empirical mean. But, how do we choose N to minimise regret over time T?

Proposition 1.2 - Naïve Heuristic (Single Test)

Consider a 2-armed bandit & the following Heuristic

Play each arm once. Pick the arm with the greatest sample mean reward (breaking ties arbitrarily) and playing that arm on all subsequent rounds.

This heuristic picks the wrong arm with probability  $\mu_2(1-\mu_1)$ . In this case the wrong arm is played T-1 times, giving a bounded regret

$$\mathcal{R}(T) \ge \underbrace{\mu_2(1-\mu_1)}_{\text{prob of wrong choice}} \cdot \underbrace{(\mu_1-\mu_2)}_{\text{Loss}} \cdot \underbrace{(T-1)}_{\text{\# steps}}$$

This regret grows linearly in T.

**Theorem 1.1 -** Chernoff Bound of a Binomial Random Variable Let  $X \sim \text{Bin}(n, \alpha \text{ with } n \in \mathbb{N}, \ \alpha \in (0, 1).$  Then

$$\forall \beta > \alpha \quad \mathbb{P}(X \ge Xn) \le e^{-nK(\beta;\alpha)}$$

where

$$K(\beta;\alpha) := \begin{cases} \beta \ln \left(\frac{\beta}{\alpha}\right) + (1-\beta) \ln \left(\frac{1-\beta}{1-\alpha}\right) & \text{if } \beta \in [0,1] \\ +\infty & \text{otherwise} \end{cases}$$

with  $x \ln(x) := 0$  if x = 0.

Similarly

$$\forall \ \beta < \alpha \quad \mathbb{P}(X \le \beta n) \le e^{-nK(\beta;\alpha)}$$

Note that  $K(\cdot;\cdot)$  is known as both relative entropy and Kullback-Leibler Divergence

### **Proposition 1.3 -** Better Heuristic (N Tests)

Consider a 2-armed bandit problem & the following heuristic

Play each arm  $N < \frac{T}{2}$ . Pick the arm with the greatest sample mean reward (breaking ties arbitrarily) and playing that arm on all subsequent rounds.

Note that  $S_1(n)$  &  $S_2(n)$  are binomial random variables with distributions  $Bin(N, \mu_1)$ ,  $Bin(N, \mu_2)$  respectively. And,  $S_1(n)$  and  $S_2(n)$  are independent of each other. Thus for  $\beta \in (\mu_2, \mu_1)$ 

$$\mathbb{P}(S_1(N) < \beta N, S_2(N) > \beta N) < e^{-N(K(\beta;\mu_1) + K(\beta;\mu_2))} = e^{-NJ(\mu_1,\mu_2)}$$

where

$$J(\mu_1, \mu_2) = \inf_{\beta \in [\mu_2, \mu_1]} (K(\beta; \mu_1) + K(\beta; \mu_2))$$

The values of  $\beta$  which solve  $J(\cdot;\cdot)$  describe the most likely ways for the event  $(S_1(N) < S_2(N))$  to occur (ie the wrong decision is made).

## **Proposition 1.4** - $Optimal\ N$

For the situation described in Proposition 1.2 we want to find N which minimises regret, given a total time horizon of T.

If the right decision is made in the end, regret only occurs during exploration and is equal to  $N \cdot (\mu_1 - \mu_2)$  (since the wrong arm is played N times).

However, if the wrong decision is made in the end, regret is equal to  $(T - N) \cdot (\mu_1 - \mu_2)$ .

Thus, the overall regret up to time T is

$$\mathcal{R}(T) = \underbrace{(T - 2N)(\mu_1 - \mu_2)\mathbb{P}(S_1(N) < S_2(N))}_{\text{if wrong decision made}} + \underbrace{N(\mu_1 - \mu_2)}_{\text{guaranteed regret}}$$

$$\simeq (\mu_1 - \mu_2)(N + Te^{-NJ(\mu_1, \mu_2)})$$

This expression is minimised for N close to the solution of  $1 = TJ(\mu_1, \mu_2)e^{-NJ(\mu_1, \mu_2)}$  (ie when  $N = \frac{\ln T}{J(\mu_1, \mu_2)} + O(1)$ ). The corresponding regret is

$$\mathcal{R}(T) = \frac{\mu - 1 - \mu_2}{J(\mu_1, \mu_2)} \ln(T) + O(1)$$

If  $\mu_1 \simeq \mu_2$  then  $J(\mu_1, \mu_2) \simeq (\mu_1 - \mu - 2)^2$  and the above regret becomes  $\mathcal{R}(T) = \frac{\ln(T)}{\mu_1 - \mu_2} + O(1)$ .

#### **UCB** Algorithm 1.5

## Remark 1.5 - UCB Algorithm

The Upper Confidence Bound Algorithm is a frequentist algorithm for solving the multi-armed bandit problem.

#### Remark 1.6 - Motivation

The problem with the heuristics in Proposition 1.2,1.3 treat the sample mean as the true mean, which is not great. Suppose we observed sample mean reward for arm i of  $\hat{\mu}_{i,n}$  after n plays. How far from the true value can  $\mu_i$  be?

$$\mathbb{P}(\mu_i > \hat{\mu}_{i,n} + x) \leq e^{-2nx^2}$$
 by Hoeffding's Inequality

Suppose the inequality holds with equality (ie most optimisite outcome). Then

$$\mathbb{P}(\mu_i > \hat{\mu}_{i,n} + x) = d \Longleftrightarrow x = \sqrt{\frac{1}{2n} \ln\left(\frac{1}{\delta}\right)}$$

This suggests a heuristic:

Play arm which maximises 
$$\hat{\mu}_{i,N_i(t)} + \sqrt{\frac{1}{2N_i(t)} \ln\left(\frac{1}{\delta}\right)}$$

where you choose  $\delta$  based on how lucky you feel.

This heuristic allows for our choice to be changed any number of times.

### **Definition 1.8** - $UCB(\alpha)$ Algorithm

Consider the set up of the multi-armed bandit problem in Proposition 1.1 and wlog that  $\mu_1 > \mu_2 \leq \cdots \leq \mu_K$ .

Consider a k-armed bandit and let  $\alpha > 0$ .

- i). In the first K rounds, play each arm once.
- ii). At the end of each round  $t \geq K$  compute the  $UCB(\alpha)$  index of each arm i defined as

$$\hat{\mu}_{i,N_i(t)} + \sqrt{\frac{\alpha \ln(t)}{2N_i(t)}}$$

iii). In round t+1 play the arm with the greatest index (breaking ties arbitrarily)

$$I(t+1) = \operatorname{argmax}_{i \in [1,K]} \left\{ \hat{\mu}_{i,N_i(t)} + \sqrt{\frac{\alpha \ln(t)}{2N_i(t)}} \right\}$$

#### 1.5.1 Analysis

#### Theorem 1.2 - Upper Bound on Regret

Consider a k-armed bandit and define  $\Delta_i := \mu_1 - \mu_i$ .

If the  $UCB(\alpha)$  algorithm is used, with  $\alpha > 1$ , then the regret in the first T rounds is bounded above by

$$\mathcal{R} \le \sum_{i=2}^{K} \left( \frac{\alpha+1}{\alpha-1} \Delta_i + \frac{2\alpha}{\Delta_i} \ln(T) \right)$$

This bounds grows logarithmically in T, which is very good.

If  $\alpha$  is taken to be large, then the regret grows faster (bad). If  $\alpha$  is small, the constant term dominates for smaller values of T (constant term blows up close to 1).

Should choose a value a bit larger than 1 (often  $\alpha = 2$ )

## **Theorem 1.3** - When a sub-optimal arm is played

Consider apply  $UCB(\alpha)$  to a k-armed bandit and define  $\Delta_i := \mu_1 - \mu_i$ . Let  $s \geq K$  (so we have completed the first stage of UCB) and suppose  $I(s+1) = j \neq 1$  (ie arm at time s+1 is suboptimal). Then one of the following is true:

- i).  $\hat{\mu}_{1,N_1(s)} \leq \mu_1 \sqrt{\frac{\alpha \ln(s)}{2N_1(s)}}$ . The sample mean reward on the optimal arm is much smaller than the true mean.
- ii).  $\hat{\mu}_{j,N_j(s)} \ge \mu_j + \sqrt{\frac{\alpha \ln(s)}{2N_j(s)}}$ . The sample mean reward on arm j is much larger than its true mean.
- iii).  $N_j(s) < \frac{2\alpha \ln(s)}{\Delta_j^2}$ . Arm j has been played very few times.

#### **Proof 1.1 -** *Theorem 1.3*

This is a proof by contradiction.

Suppose  $I(s+1)=j\neq 1$  but that none of the three inequalities holds. Then

$$\frac{\hat{\mu}_{1,N_{1}(s)} + \sqrt{\frac{\alpha \ln(s)}{2N_{1}(s)}}}{2N_{1}(s)} > \mu_{1} \qquad \text{by not i})$$

$$= \mu_{j} + \Delta_{j} \qquad \text{by def. of } \Delta_{j}$$

$$\geq \mu_{j} + \sqrt{\frac{2\alpha \ln(s)}{N_{j}(s)}} \qquad \text{by not iii})$$

$$\geq \hat{\mu}_{1,N_{1}(s)} - \sqrt{\frac{\alpha \ln(s)}{2N_{1}(s)}} + \sqrt{\frac{2\alpha \ln(s)}{N_{j}(s)}} \qquad \text{by not iii})$$

$$\geq \hat{\mu}_{1,N_{1}(s)} + \left(\sqrt{2} - \frac{1}{\sqrt{2}}\right) \sqrt{\frac{\alpha \ln(s)}{N_{1}(s)}}$$

$$= \hat{\mu}_{j,N_{j}(s)} + \sqrt{\frac{\alpha \ln(s)}{2N_{j}(s)}}$$

$$= \hat{\mu}_{j,N_{j}(s)} + \sqrt{\frac{\alpha \ln(s)}{2N_{j}(s)}}$$

But, this implies that the  $UCB(\alpha)$  index of arm 1 at the end of round s is greater than that of arm j. Hence arm j would not be played in time slot s+1.

Theorem 1.4 - Counting Lemma

Let  $\{I(t)\}_{t\in\mathbb{N}}$  be a  $\{0,1\}$ -valued sequence and  $N(t):=\sum_{s=1}^t I(s)$ . Then

$$\forall t, u \in \mathbb{N} \quad N(t) \le u + \sum_{s=u+1}^{t} I(s) \mathbb{1}\{N(s-1) \ge u\}$$

with an empty sum defined to be zero.

#### **Proof 1.2 -** *Theorem 1.4*

Fix  $t, u \in \mathbb{N}$ . There are two possibilities

Case 1  $N(t) \leq u$ . (Have not reached u yet)

Case  $2 \exists s \in [1,t]$  st N(s) > u. (Already reached u). Let  $s^*$  denote the smallest such s. Then it must be true that  $N(s^* - 1) = u$  and  $s^* \ge u + 1$ . Hence

$$\begin{split} N(t) &= \sum_{s=1}^{s^*-1} I(s) + \sum_{s=s^*}^t I(s) \\ &= N(s^*-1) + \sum_{s=s^*}^t I(s) \underbrace{\mathbbm{1}\{N(s-1) \geq u\}}_{\text{true for all in sum}} \\ &\leq u + \sum_{s=u+1}^t I(s) \mathbbm{1}\{N(s-1) \geq u\} \quad \text{since } s \geq u+1 \end{split}$$

**Theorem 1.5 -** Concentration Inequalities for Sample Means

$$\mathbb{P}\left(\hat{\mu}_{j,N_{j}(s)} \ge u_{j} + \sqrt{\frac{\alpha \ln s}{2N_{j}(s)}}\right) \le e^{-\alpha \ln s} = s^{-\alpha}$$

$$\mathbb{P}\left(\hat{\mu}_{1,N_{1}(s)} \le u_{1} - \sqrt{\frac{\alpha \ln s}{2N_{1}(s)}}\right) \le e^{-\alpha \ln s} = s^{-\alpha}$$

#### **Proof 1.3** - *Theorem 1.5*

The proof is immediate from *Hoeffding's Inequality*, which is applicable since the  $X_j$  are iid and take values in  $\{0,1\} \subseteq [0,1]$ .

**Proof 1.4** - Theorem 1.2 Fix  $t \in \mathbb{N}$  adn take  $u_{t,j} := \left\lceil \frac{2\alpha \ln(t)}{\Delta_j^2} \right\rceil$ .

By Theorem 1.4 we have that

$$N_j(t) \le u + \sum_{s=u+1}^t \mathbb{1}\{(N_j(s-1) \ge u_{t,j}) \& (I(s) = j)\}$$

Both sides involve random variables. Taking expectations we get

$$\mathbb{E}[N_j(t)] \le u + \sum_{s=u}^{t-1} \mathbb{P}\{(N_j(s) \ge u_{y,j}) \& (I(s+1) = j)\}$$

By Theorem 1.3 and the definition of u, IF I(s+1)=j and  $N_j(s)\geq u$  then

$$\hat{\mu}_{1,N_1(s)} \le u_1 - \sqrt{\frac{\alpha \ln(s)}{2N_1(s)}} \quad \text{or} \quad \hat{\mu}_{j,N_j(s)} > \mu_j + \sqrt{\frac{\alpha \ln(s)}{2N_j(s)}}$$

Thus

$$\mathbb{E}[N_{j}(t)] \leq u_{t,j} + \sum_{s=u_{t,j}}^{t-1} \left[ \mathbb{P}\left(\hat{\mu}_{1,N_{1}(s)} \leq \mu_{1} - \sqrt{\frac{\alpha \ln(s)}{2N_{1}(s)}}\right) + \mathbb{P}\left(\hat{\mu}_{j,N_{j}(s)} > \mu_{j} - \sqrt{\frac{\alpha \ln(s)}{2N_{j}(s)}}\right) \right]_{\hat{\mu}_{j} \text{ is unusually large}}$$

By Theorem 1.5

$$\mathbb{E}[N_j(t)] \leq u + \sum_{s=u}^{t-1} 2s^{-\alpha}$$

$$\leq u + \int_{u-1}^{\infty} 2s^{-\alpha} ds \quad \text{assumption } \alpha > 1 \text{ required here}$$

$$= u + \frac{2(u-1)^{-(\alpha-1)}}{\alpha - 1}$$

$$\leq u + \frac{2}{\alpha - 1} \quad \text{since } u \geq 2 \implies (u-1)^{-(\alpha-1)} \leq 1$$

Thus

$$\forall j \in [2, K] \quad \mathbb{E}[N_j(t)] \le u + \frac{2}{\alpha - 1} \le \frac{2\alpha \ln(t)}{\Delta_j^2} + 1 + \frac{2}{\alpha - 1}$$

A regret of  $\Delta_j := \mu_1 - \mu_j$  is incurred every time arm j is played. Hence the total regret up to time t is bounded by

$$\mathcal{R}(t) := \sum_{i=2}^{K} \Delta_{i} \mathbb{E}[N_{i}(t)]$$

$$\leq \sum_{i=2}^{K} \left( \frac{2\alpha \ln(t)}{\Delta_{i}} + \frac{\alpha+1}{\alpha-1} \Delta_{i} \right)$$

**Remark 1.7** - Is there an algorithm which achieves lower regret? No. There is no algorithm which has regret growing slower than  $\ln(T)$ .

## 2 Probability

#### **Definition 2.1 -** Random Process

A Random Process is a collection of random variables indexed by time  $\{X_t\}_{t\in T}$  (e.g. flipping a coin several times). Each of these random variables can take a value from a state space S. A random process a Discrete Time Process if the index set T is discrete. A random process a Continuous Time Process if the index set T is continuous.

#### 2.1 Probability Inequalities

**Remark 2.1** - We can use the moments of a random variable to determine bounds on the probability of it taking values in a certain set.

Theorem 2.1 - Markov's Inequality

Let X be a non-negative random variable. Then

$$\forall c > 0 \quad \mathbb{P}(X \ge c) \le \frac{\mathbb{E}(X)}{c}$$

Proof

Consider an event A and define its indicator  $\mathbb{1}(A)(\omega) := \begin{cases} 1 & \omega \in A \\ 0 & \omega \notin A \end{cases}$ . Fix c > 0, then

$$\begin{array}{rcl} \mathbb{E}(X) & \geq & \mathbb{E}[X \mathbbm{1}(X \geq c)] \\ & \geq & \mathbb{E}[c \mathbbm{1}(X \geq c)] \\ & = & c \mathbb{P}(X \geq c) \\ \Longrightarrow & \mathbb{P}(X \geq c) & \leq & \frac{1}{c} \mathbb{E}(X) \end{array}$$

#### **Theorem 2.2** - Chebyshev's Inequality

Let X be a random-variable with finite mean and variance. Then

$$\forall c > 0 \quad \mathbb{P}(|X - \mathbb{E}(X)| \ge c) \le \frac{\operatorname{Var}(X)}{c^2}$$

Proof

Note that the events  $|X - \mathbb{E}(X)| \ge c$  and  $(X - \mathbb{E}(X))^2 \ge c^2$ ) are equivalent. Note that  $\text{Var}([X - \mathbb{E}(X)]^2) = \text{Var}(X)$ . Then the result follows by Markov's Inequality.

## Theorem 2.3 - Chebyshev's Inequality for Sum of IIDs

Let  $X_1, \ldots, X_n$  be IID random variables with finite mean  $\mu$  and finite variance  $\sigma^2$ .

$$\forall c > 0 \quad \mathbb{P}\left(\left|\left(\sum_{i=1}^{n} X_i\right) - n\mu\right| \ge nc\right) \le \frac{\sigma^2}{nc^2}$$

Proof

This is proved by extending the proof of Theorem 2.2 and noting that the variance of a sum of IIDs is the sum of the individual variances.

#### **Theorem 2.4** - Chernoff Bounds

Let X be a random variable whose moment-generating function  $\mathbb{E}[e^{\theta X}]$  is finite  $\forall \theta$ . Then

$$\forall c \in \mathbb{R} \quad \mathbb{P}(X \ge c) \le \inf_{\theta > 0} e^{-\theta c} \mathbb{E}(e^{\theta X}) \quad \text{and} \quad \mathbb{P}(X \le c) \le \inf_{\theta < 0} e^{-\theta c} \mathbb{E}(e^{\theta X})$$

Proof

Note that the events  $X \geq c$  and  $e^{\theta X} \geq e^{\theta c}$  are equivalent for all  $\theta > 0$ . The result follows by applying *Markov's Inequality* to  $r^{\theta X}$  and taking the best bound over all possible  $\theta$ .

$$\begin{array}{lcl} \mathbb{P}(X \geq c) & = & \mathbb{P}(e^{\theta X} \geq e^{\theta c}) \\ & \leq & e^{-\theta c} \mathbb{E}(e^{\theta X}) \\ & \leq & \inf_{\theta < 0} e^{-\theta c} \mathbb{E}(e^{\theta X}) \end{array}$$

#### **Theorem 2.5 -** Chernoff Bounds for Sum of IIDs

Let  $X_1, \ldots, X_n$  be IID random variables. Then  $\forall c \in \mathbb{R}$ 

$$\mathbb{P}\left(\sum_{i=1}^{n} X_{i} \ge nc\right) \le \inf_{\theta > 0} e^{-n\theta c} \left(\mathbb{E}\left[e^{\theta X}\right]\right)^{n}$$

$$\mathbb{P}\left(\sum_{i=1}^{n} X_{i} \le nc\right) \le \inf_{\theta < 0} e^{-n\theta c} \left(\mathbb{E}\left[e^{\theta X}\right]\right)^{n}$$

## Theorem 2.6 - Jensen's Inequality

Let f be a Convex Function and X be a random variable. Then

$$\mathbb{E}[f(X)] \ge f(\mathbb{E}[X])$$

## Theorem 2.7 - Bound on Moment Generating Function

Let X be a random variable taking values in [0,1] with finite expected value  $\mu$ . Then we can bound the MGF of the centred random variable with

$$\forall \ \theta \in \mathbb{R} \quad \mathbb{E}\left[e^{\theta(X-\mu)}\right] \le e^{\theta^2/8}$$

Proof (of weaker version)

Let  $X_1$  be an independent copy of X, so both have mean  $\mu$ . We can easily verify that  $f(x) = e^{\theta x}$  is a convex function for all  $\theta \in \mathbb{R}$ . By Jensen's Inequality to  $f(\cdot)$  and  $X_1$ 

$$\mathbb{E}[e^{-\theta X_1}] \ge e^{-\theta \mathbb{E}[X_1]} = e^{-\theta \mu} \quad (1)$$

Consequently

$$\mathbb{E}[e^{\theta(X-X_1)}] = \mathbb{E}[e^{\theta X}] \cdot \mathbb{E}[e^{-\theta X_1}] \quad \text{by independence}$$

$$\geq \mathbb{E}[e^{\theta X}] \cdot e^{-\theta \mu} \quad \text{by (1)}$$

$$= \mathbb{E}[e^{\theta(X-\mu)}]$$

$$\implies \mathbb{E}[e^{\theta(X-X_1)}] \geq \mathbb{E}[e^{\theta(X-\mu)}]$$

Since  $X, X_1 \in [0, 1]$  then  $(X - X_1) \in [-1, 1]$ . As  $X, X_1$  have the same distribution  $\mathbb{E}(X - X_1) = 0$  and the distribution is symmetric around the mean.

Define random variable S which is independent of  $X, X_1$  and takes values  $\{-1, 1\}$ , each with probability  $p = \frac{1}{2}$ .  $S(X - X_1)$  has the same distribution as  $(X - X_1)$  due to independence of S and symmetry of  $(X - X_1)$ . Hence

$$\mathbb{E}[e^{\theta(X-X_1)}] = \mathbb{E}[e^{\theta S(X-X_1)}]$$
 by identical distribution 
$$\leq \mathbb{E}[e^{\theta S}]$$
 (2) since  $(X-X_1) \in [-1,1]$  by def. of expectation 
$$\Rightarrow \mathbb{E}[e^{\theta(X-X_1)}] \leq \frac{1}{2}(e^{\theta} + e^{-\theta})$$

Note that  $f(x) = e^x + e^{-x}$  is increasing for  $x \in (0, \infty)$ ; decreasing for  $x \in (-\infty, 0)$ ; and symmetric around 0.

Using a Taylor Series we an observed that

$$\begin{array}{rcl} \frac{1}{2}(e^{\theta}-e^{-\theta}) & = & \displaystyle\sum_{n=0}^{\infty}\frac{\theta^{2n}}{(2n)!} & \text{by Taylor expansion of} e^{x} \\ & \leq & \displaystyle\sum_{n=0}^{\infty}\frac{(\theta^{2}/2)^{n}}{n!} \\ & \stackrel{\text{def.}}{=} & e^{\theta^{2}/2} \\ \Longrightarrow & \frac{1}{2}(e^{\theta}+e^{-\theta}) & \leq & e^{\theta^{2}/2} \end{array}$$

Combining all these results we get

$$\mathbb{E}[e^{\theta(X-\mu)}] \le \mathbb{E}[e^{\theta(X-X_1)}] \le \frac{1}{2}(e^{\theta} + e^{-\theta}) \le e^{\theta^2/2}$$

$$\implies \mathbb{E}[e^{\theta(X-\mu)}] \le e^{\theta^2/2}$$

#### **Theorem 2.8** - Hoeffding's Theorem

Let  $X_1, \ldots, X_n$  be IID random variables taking values in [0,1] and with finite expected value  $\mu$ . Then

$$\forall t > 0 \quad \mathbb{P}\left(\sum_{i=1}^{n} (X_i - \mu) > nt\right) \le e^{-2nt^2}$$

Proof

From Chernoff's Bound we have that

$$\forall \ \theta > 0 \quad \mathbb{P}\left(\sum_{i=1}^{n} (X_i - \mu) > nt\right) \le e^{-\theta nt} \left(\mathbb{E}[e^{\theta(X - \mu)}]\right)^n$$

Using Theorem 2.7 to bound the moment generating function, we get

$$\forall \theta > 0 \quad \mathbb{P}\left(\sum_{i=1}^{n} (X_i - \mu) > nt\right) \le e^{-\theta nt} \cdot e^{n\frac{\theta^2}{8}} = e^{n\left(-\theta t + \frac{1}{8}\theta^2\right)}$$

Thus, by taking logs and rearranging, we get

$$\forall \theta > 0 \quad \frac{1}{n} \log \mathbb{P} \left( \sum_{i=1}^{n} (X_i - \mu) > nt \right) \le -\theta t + \frac{\theta^2}{8}$$

We have that  $-\theta t + \frac{\theta^2}{8}$  is minimised at  $\theta = 4t$  which is positive if t is positive. Thus, by applying this bound and substituting  $\theta = 4t$  we get

$$\forall \theta > 0 \quad \mathbb{P}\left(\sum_{i=1}^{n} (X_i - \mu) > nt\right) \le e^{n\left(-4t^2 + \frac{1}{8}(16t^2)\right)} = e^{n(-4t^2 + 2t^2)} = e^{-2nt^2}$$

## 2.2 Markov Processes

#### **Definition 2.2 -** Markov Property

A random process has the  $Markov\ Property$  if the conditional probability of a future state  $\underline{\text{only}}$  depends on the current state.

$$\mathbb{P}(X_{t+1} = y | X_t = x_t, X_{t-1} = x_{t-1}) = \mathbb{P}(X_{t+1} = y | X_t = x_t)$$

A random process with the Markov Property is called a Markov Process/Chain.

Remark 2.2 - On this course we only deal with discrete time markov chains

#### **Definition 2.3 -** Transience

A state  $x \in S$  is Transient if  $\mathbb{P}(\exists t > 0 : X_t = x | X_0 = x) < 1$ . The number of times the markov chain returns to a transient state is finite, with probability 1.

#### **Definition 2.4 -** Recurrent

A state  $x \in S$  is Recurrent if  $\mathbb{P}(\exists t > 0 : X_t = x | X_0 = x) = 1$ . The number of times the markov chain returns to a recurrent state is <u>infinite</u>, with probability 1.

Every markov chain, with a finite state space S, has a recurrent communicating class.

#### **Definition 2.5 -** Communication Class

We say  $y \in S$  is Accessible from  $x \in S$  if  $\exists t \ge 0$  st  $[P^t]_{xy} > 0$ .

We say x and y communicate (denoted xCy) if: x is accessible from y and y is accessible from x.

Communication is an equivalence relation on the state space S. Hence, communication partitions S into equivalence classes called Communication Classes. All elements of a Communication Class communicate with all other elements in the class, it is possible for elements to be accessible from another class but not for those elements to communicate.

If one state in a Communicating Class is Transient/Recurrent then all states are in that class. If a Markov Chain has only one communicating class it is called Irreducible.

#### 2.2.1 Discrete Time Markov Chains

Proposition 2.1 - Characterising a Discrete Time Markov Process

A Discrete Time Markov Process can be characterised by the set of all 1-step conditional probabilities

$$\mathbb{P}(X_{t+1} = y | X_t = x) \ \forall \ x, y \in S$$

A markov chain is *time-homogeneous* if the 1-step conditionals only depend on x, y and not on t ( $\mathbb{P}(X_{t+1} = y | X_t = x) = \mathbb{P}(X_1 = t | X_0 = x)$ ). The 1-step conditional probabilities of a *time-homogeneous markov process* can be specified in an  $|S| \times |S|$  matrix P where

$$p_{x,y} = \mathbb{P}(X_{t+1} = y | X_t = x)$$

P is a Stochastic Matrix.

**Proposition 2.2** - n-Step Transition Probabilities from 1-Step Transition Matrix Let P be the 1-step transition matrix for a time-homogeneous. The 2-step transition probabilities (ie  $\mathbb{P}(X_{t+2}=z|X_t=x)$ ) can be found as

$$\mathbb{P}(X_{t+2}=z|X_t=x) = \mathbb{P}(X_2=z|X_0=x) \text{ by time-homogeneity}$$

$$= \sum_{y \in S} \mathbb{P}(X_2=z,X_1=y|X_t=x)$$

$$= \sum_{y \in S} \mathbb{P}(X_1=y|X_0=x)\mathbb{P}(X_2=z|X_1=t,X_0=x)$$

$$= \sum_{y \in S} \mathbb{P}(X_1=y|X_0=x)\mathbb{P}(X_2=z|X_1=y)$$

$$= \sum_{y \in S} p_{xy}p_{yz}$$

$$\equiv [P^2]_{xz}$$

This can be generalise for the n-step transition probabilities with

$$\mathbb{P}(X_{t+n} = z | X_t = x) = [P^n]_{xz}$$

**Proposition 2.3** - Any Joint Probability from 1-Step Transition Matrix

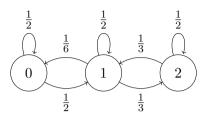

For a time homogeneous markov process the joint distribution of any transition can be computed by considering the individual steps of the transition.

$$\mathbb{P}(X_{n_0} = x_0, X_{n_1} = x_1, X_{n_2} = x_2, \dots) = \mathbb{P}(X_{n_0} = x_0) \cdot [P^{n_0 - n_1}]_{x_0 x_1} \cdot [P^{n_1 - n_2}]_{x_1 x_2} \dots$$

#### **Proposition 2.4 -** State Diagram Representation

A graph/automata can be drawn to represent the transition probability matrix P. A node is assigned for each member of the state space S and an arrow is drawn between each pair of nodes (x, y) where  $P_{xy} \neq 0$ . Generally the value of  $P_{xy}$  is denoted on the arrow.

$$P = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0\\ \frac{1}{6} & \frac{1}{2} & \frac{1}{3}\\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix}$$

#### **Definition 2.6** - Invariant Distribution

Let  $\mu(t)$  denote the probability distribution of random variable X (i,e,  $\mu_x(t) = \mathbb{P}(X_t = x)$ ). Then

$$\begin{array}{rcl} \boldsymbol{\mu}(t+1) & = & \mathbb{P}(X_{t+1}=y) = \sum_{x \in S} \mathbb{P}(X_t=x, X_{t+1}=y) = \sum_{x \in S} \mu_x(t) p_{xy} = \boldsymbol{\mu}(t) P \\ \Longrightarrow & \boldsymbol{\mu}(t+1) & = & \boldsymbol{\mu}(t) P \end{array}$$

A distribution  $\pi$  on the state space is called an *Invariant Distribution* if  $\pi = \pi P$ . If  $X_t$  has distribution  $\pi$  so will  $X_{t+1}, \ldots$  Every markov chain with a *finite* state space S has an *invariant distribution*. (Not necessarily true if S is infinite).

#### Proposition 2.5 - Finding an Invariant Distribution

If an *Invariant Distribution* it is easy to find by solving  $\pi P = \pi$  and using normalising constant  $\sum_{x \in S} \pi_x = 1$ .

Remark 2.3 - If a Markov chain is irreducible, its invariant distribution (if one exists) is unique

If a *Markov Chain* is irreducible and has a finite state space, then it has a unique invariant distribution.

## Example 2.1 - Markov Chains

- The Asymmetric Simple Random Walk on Z is irreducible, transient and has no invariant distribution.
- The Symmetric Simple Random Walk on  $\mathbb{Z}$  is irreducible, recurrent and has no invariant distribution.

#### **Theorem 2.9 -** Ergodic Theorem for Markov Chains

Let  $\{X_t\}_{t\in\mathbb{N}}$  be an irreducible markov chain on state space S (not necessarily finite) with unique invariant distribution  $\pi$ . Then

$$\forall x \in S \quad \lim_{t \to \infty} \frac{1}{t} \sum_{s=1}^{t} \mathbb{1}(X_s = x) = \pi_x$$

i.e. The fraction of time spend in state  $x \in S$  tends to  $\pi_x$  in the long run.

#### **Definition 2.7 -** Period

The Period of a state  $x \in S$  is the greatest common divisor of all possible return times to x

$$Period(x) := gcd(\{t > 0 : \mathbb{P}(X_t = x | X_0 = x) > 0\})$$

A state  $x \in S$  is Aperiodic if Period(x) = 1. An irreducible markov chain is aperiodic if all its states are aperiodic.

All states in a *communicating class* have the same period.

**Proposition 2.6** - Marginal Distribution of Irreducible, Aperiodic Markov Chain If an irreducible, aperiodic Markov Chain has an invariant distribution  $\pi$ , then

$$\forall x \in S \quad \mu_x(t) \stackrel{t \to \infty}{\longrightarrow} \pi_x$$

## **Definition 2.8** - Reversibility

A markov chain  $\{X_t\}_{t\in\mathbb{Z}}$  is *Reversible* if all joint distributions are the same forwards and backwards in time. (i.e. the distribution of the chain is the same if it was reversed). An irreducible markov chain  $\{X_t\}_{t\in\mathbb{Z}}$  with transition matrix P is reversible iff

$$\exists \boldsymbol{\pi} \quad \text{st} \quad \pi_x p_{xy} = \pi_y p_{yx} \ \forall \ x, y \in S$$

This is the *Local/Detailed Balance Equation*. Note that this is a system of  $\binom{|S|}{2}$  equations which need to be consistent for reversibility to exist.

#### 2.2.2 Continuous Time Markov Process

**Definition 2.9 -** Continuous Time Markov Process

A stochastic process  $\{X_t\}_{t\in\mathbb{R}}$  is a Continuous Time Markov Process on state space s if

$$\forall s < t \& x, y \in S \quad \mathbb{P}(X_t = y | X_s = x, X_u, u < s) = \mathbb{P}(X_t = y | X_s = x)$$

ie future values only depend on the present value and not past.

If  $\forall t, s, x, y \ \mathbb{P}(X_t = y | X_s = x)$  depends only on x, y, t - s (observed values & change in time) then the process is Time-Homogeneous.

For Time-Homogenous Markov Processes we let P(t) denote the stochastic matrix with the probability of each possible transition after t time  $[P(t)]_{xy} = \mathbb{P}(X_t = y|X_0 = x)$ .

**Remark 2.4** - A Time-Homogenous Markov Process is completely described by its initial condition and the family of transition probability matrices  $\{P(t): t \geq 0\}$  This set of matrices  $\{P(t): t \geq 0\}$  is uncountably large.

#### **Definition 2.10 -** Chapman-Kolmogorov Equations

For a Time-Homogeneous Markov Process the family of stochastic matrices  $\{P(t): t \geq 0 \text{ satisfy the following:} \}$ 

i). 
$$P(0) = I$$
;

ii). 
$$P(t+s) = P(t)P(s) = P(s)P(t)$$

Hence

$$\frac{d}{dt}P(t) := \lim_{\delta \to 0} \frac{P(t+\delta) - P(t)}{\delta} = \lim_{\delta \to 0} \frac{\overbrace{P(t)P(\delta)}^{\text{ii}} - P(t)}{\delta} = P(t) \lim_{\delta \to 0} \frac{(P(\delta) - I)}{\delta}$$

Suppose that 
$$Q := \lim_{\delta \to 0} \frac{P(\delta) - P(0)}{\delta} = \lim_{\delta \to 0} \frac{P(\delta) - \overbrace{I}^{(i)}}{\delta}$$
 exists.

Then P(t) solve the following differential equations, known as the *Chapman-Kolmogorov* Equations

$$\frac{d}{dt}P(t) = \underbrace{P(t)Q}_{\text{forward eqn.}} = \underbrace{QP(t)}_{\text{backward eqn.}}$$

The solution to these equations is

$$P(t) = P(0)e^{Qt} = e^{Qt}P(0) = e^{Qt}I = e^{Qt}$$

N.B. Q is called the Rate Matrix or Infinesimal Generator of the markov process.

## Proposition 2.7 - Properties of the Rate Matrix, Q

Let Q be the rate matrix of a continuous-time markov process. Q has the following properties

- If  $n \neq y$  then  $q_{xy} := \lim_{\delta \to 0} \frac{[P(\delta)]_{xy} 0}{\delta} \ge 0$ . (The off-diagonal elements are non-negative).
- $\forall x \in S$ ,  $\sum_{y \in S} q_{xy} = \lim_{\delta \to 0} \frac{1-1}{\delta} = 0$ . The rows of Q sum to 0.
- Thus, the diagonal entries  $q_{xx}$  are negative. (We denote  $-q_{xx}$  by  $q_x$ )

#### **Proposition 2.8** - Interpreting the Rate Matrix Q

Let Q be the rate matrix of a continuous-time markov process.

If the markov process enters state x at time t, it will remain in x for a random time which is distributed  $\text{Exp}(q_x)$ . (Note that  $q_x := -q_x x$ ).

It the jumps to state y with probability  $\frac{q_x y}{q_x}$ , independent of the past.

#### **Definition 2.11 -** Invariant Distributions

Suppose a Continuous-Time Markov Process starts with distribution  $\mu(0)$  on state space S (i.e.  $\mathbb{P}(X_0 = x) = [\mu(0)]_x$ ). Then, the distribution of  $X_t$  is  $\mu(t) := \mu(0)P(t) = \mu(0)$ 

If there exists a distribution  $\pi$  on the state space S st  $\forall$   $t \geq 0$   $\pi = \pi P(t) = \pi \underbrace{e^{Qt}_{CK \text{ Eqns}}}_{CK \text{ Eqns}}$ , then  $\pi$  is

an Invariant Distribution. This distribution is invariant wrt time.

If a markov process has a finite state space then it definitely has an invariant distribution. *Invariant Distributions* are not guaranteed to be unique.

## Proposition 2.9 - Finding an Invariant Distribution

Starting with  $\pi = \pi e^{Qt}$  we find that differentiating wrt t and then evaluating at time t = 0 we get  $\mathbf{0} = \pi Q$  (The Global Balance Equations). This system of equations can be solved to find an *Invariant Distribution*.

A markov process is reversible iff there exists a distribution  $\pi$  on S which satisfies  $\pi_x q_{xy} = \pi_y q_{yx} \ \forall \ x, y \in S$  (Local balance equations). Solving this system of equations will also find an *Invariant Distribution* but it is not guaranteed to have a solution.

#### Theorem 2.10 - Ergodic Theorem

Let  $[X_t]_{t\in\mathbb{R}^+}$  is an *Irreducible Markov Process* on a state space S and has an invariant distribution  $\pi$ . Then

$$\forall x \in S \quad \pi_x = \lim_{t \to \infty} \frac{1}{t} \int_0^t \mathbb{1}(X_s = x) ds$$

Moreover, for an arbitrary initial distribution  $\mu(0)$ ,  $\mu(t)$  converges to  $\pi$  pointwise (i.e.  $\mu_r(t) \stackrel{t \to \infty}{\longrightarrow} \pi_r$ )

#### 2.2.3 Poisson Process

#### **Definition 2.12 -** Counting Process

A Counting Process is a stochastic process  $\{N(t)\}_{t\in\mathbb{R}}$  st

- i). N(0) = 0 and  $N(t) \in \mathbb{Z}$  for all  $t \geq 0$ ; and,
- ii). N(t) is a non-decreasing function of t.

#### **Definition 2.13 -** *Independent Increments*

A Process  $\{N(t)\}_{t\in\mathbb{R}^+}$  is said to have Independent Increments if  $\forall s \in (0,t), (N(t)-N(s))$  is independent of  $\{N(u): u \in [0,s]\}.$ 

#### **Definition 2.14 -** Poisson Process

A Poisson Process is a counting process  $\{N(t)\}_{t\in\mathbb{R}^+}$  which has independent increments and at least one of the following equivalence statements are true

- $\forall t \in [0, t] \quad (N(t) N(s)) \sim \text{Po}(\lambda(t s)).$
- $\mathbb{P}(N(t+\delta) N(t) = 1) = \lambda \delta + o(\delta) \text{ and}$   $\mathbb{P}(N(t+\delta) - N(t) = 0) = 1 - \lambda \delta + o(\delta) \text{ and}$  $\mathbb{P}(N(t+\delta) - N(t) \ge 2) = o(\delta).$
- The <u>times between successive increments</u> of the process  $N(\cdot)$  are iid  $\text{Exp}(\lambda)$  random variables.

The parameter  $\lambda \in \mathbb{R}^{>0}$  is called the *rate* of the poisson process. *Poisson Processes* are continuous time markov chains.

#### Example 2.2 - Poisson Process

Counting the number of cars which have passed a given point over time.

### **Proposition 2.10 -** Properties of Poisson Processes

Define  $\{N(t)\}_{t\in\mathbb{R}^+}$  to be a *Poisson Process* with rate  $\lambda$ . Then the following properties hold

- i). The counting process  $\{N(\beta t)\}_{t\in\mathbb{R}^+}$ , with  $\beta > 0$ , is a Poisson Process with rate  $\beta\lambda$ .
- ii). If  $\{N_1(t)\}_{t\in\mathbb{R}^+}$  and  $\{N_2(t)\}_{t\in\mathbb{R}^+}$  are independent poisson processes with rates  $\lambda_1$  and  $\lambda_2$ , respectively, then  $\{N(t):=N_1(t)+N_2(t)\}_{t\in\mathbb{R}^+}$  is a poisson process with rate  $\lambda:=\lambda_1+\lambda_2$ .
- iii). Let  $X_1, X_2, \ldots$  be a sequence of iid Bern(p) random vairables, independent of  $N(\cdot)$ . Define  $N_1(t) := \sum_{i=1}^{N(t)} X_i$  and  $N_2(t) := \sum_{i=1}^{N(t)} (1-X_i)$  (These are called Bernoulli Thinnings). These assign increments in  $N(\cdot)$  randomly to either  $N_1$  or  $N_2$  (with probability p). Then,  $N_1(\cdot)$  and  $N_2(\cdot)$  are independent poisson processes with rates  $\lambda p$  and  $\lambda(1-p)$ , respectively.

## 0 Reference

#### **Definition 0.1 -** Stochastic Matrix

A matrix is called a *Stochastic matrix* if:

- i). All elements are non-negative.
- ii). All rows sum to 1.

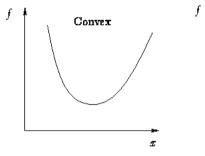

## **Definition 0.2 -** Convex Function

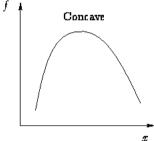

A function  $f: \mathbb{R} \to (\mathbb{R} \cup \{+\infty\})$  is Convex if,  $\forall x, y \in \mathbb{R}, \alpha \in [0,1]$ , we have

$$f(\alpha x + (1 - \alpha)y) \le \alpha f(x) + (1 - \alpha)f(y)$$

A smooth function f is convex iff f is twice differentiable and  $f''(x) \ge 0 \ \forall \ x \in \mathbb{R}$ .

Visually, a function is convex if you can draw a line between any two points on the function and the function lies below the line.

#### **Definition 0.3** - Equivalence Relation

A relation is an Equivalence Relation if it is

- i). Reflexive:  $i \leftrightarrow i$ .
- ii). Symmetric: If  $i \to j$  then  $j \to i$ .
- iii). Transitive: If  $i \to j$  and  $j \to k$  then  $i \to k$ .

#### **Definition 0.4** - Simple Random Walk

A Simple Random Walk is a random walk which moves only one step at a time. (i.e.  $X_{t+1} = X_t \pm 1$ ). A probability p is defined for  $\mathbb{P}(X_{t+1} = X_t + 1)$ , this means 1 - p is the probability of stepping in the other direction. A Simple Random Walk is Assymetric if  $p \neq p - 1$ .

**Definition 0.5** - Matrix Exponential,  $e^X$ 

Let X be a matrix then we define the Matrix Exponential as  $e^X := I + X + \frac{X^2}{2!} + \dots$ 

#### 0.1 Notation

 $\mid p_{x,y} \mid \mathbb{P}(X_{t+1} = x | X_t = y)$  for a time homogenous markov process  $\mid$ 

## 0.1.1 Asymptotic Notation

## **Definition 0.6** - Oh Notation

Let 
$$f, g: \mathbb{R}^+ \to \mathbb{R}$$
.

We say 
$$f = o(g)$$
 (little oh of  $g$ ) at 0 if  $\frac{f(x)}{g(x)} \xrightarrow{x \to 0} 0$ .

We say 
$$f = O(g)$$
 (big oh of g) at 0 if  $\exists c > 0$  st  $|f(x)| \le c|g(x)|$  in a neighbourhood of 0.  $f = o(g)$  at infinity and  $f = O(g)$  at infinity are defined analogously.

#### **Definition 0.7** - Omega Notation

Let 
$$f, g: \mathbb{R}^+ \to \mathbb{R}$$
.

We say  $g = \omega(g)$  if o(f) and we say  $f = \Omega(g)$  if g = O(f).

Example 0.1 - Oh & Omega Notation

Define f(x) = x,  $g(x) = \sin(x)$  and  $h(x) = x^2$ .

Then, g = O(f) at 0 and g = o(f) at infinity. h = o(f) at 0 and  $h = \omega(f)$  at infinity.
